4	Splitting time at a specific date	7
5	Competing risks — multiple types of events	10
6	Multiple events of the same type (recurrent events)	13

## 1 Follow-up data in the Epi package

In the Epi-package, follow-up data is represented by adding some extra variables to a dataframe. Such a dataframe is called a Lexis object. The tools for handling follow-up data then use the structure of this for special plots, tabulations etc.

Follow-up data basically consists of a time of entry, a time of exit and an indication of the status at exit (normally either "alive" or "dead"). Implicitly is also assumed a status *during* the follow-up (usually "alive").

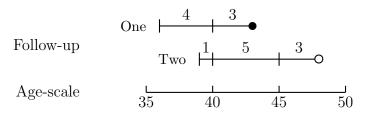

Figure 1: Follow-up of two persons

### 2 Timescales

A timescale is a variable that varies deterministically *within* each person during follow-up, *e.g.*:

- Age
- Calendar time
- Time since treatment
- Time since relapse

All timescales advance at the same pace, so the time followed is the same on all timescales. Therefore, it suffices to use only the entry point on each of the time scale, for example:

- Age at entry.
- Date of entry.
- Time since treatment (at treatment this is 0).
- Time since relapse (at relapse this is 0)...

In the Epi package, follow-up in a cohort is represented in a Lexis object. A Lexis object is a dataframe with a bit of extra structure representing the follow-up. For the nickel data we would construct a Lexis object by:

2 Timescales

The entry argument is a named list with the entry points on each of the timescales we want to use. It defines the names of the timescales and the entry points. The exit argument gives the exit time on one of the timescales, so the name of the element in this list must match one of the neames of the entry list. This is sufficient, because the follow-up time on all time scales is the same, in this case ageout - agein. Now take a look at the result:

```
look at the result:
> str( nickel )
'data.frame':
                     679 obs. of 7 variables:

6 1889.915 21.2877 44.3314 62.5413
```

The Lexis object nicL has a variable for each timescale which is the entry point on this timescale. The follow-up time is in the variable lex.dur (duration).

There is a summary function for Lexis objects that list the numer of transitions and records as well as the total follow-up time:

```
> summary( nicL )
```

```
Transitions:
```

To

```
From 0 1 Records: Events: Risk time: Persons: 0 542 137 679 137 15348.06 679
```

#### Rates:

То

```
From 0 1 Total 0 0 0.01 0.01
```

We defined the exit status to be death from lung cancer (ICD7 162,163), i.e. this variable is 1 if follow-up ended with a death from this cause. If follow-up ended alive or by death from another cause, the exit status is coded 0, i.e. as a censoring.

Note that the exit status is in the variable lex.Xst (eXit status. The variable lex.Cst is the state where the follow-up takes place (Current status), in this case 0 (alive).

It is possible to get a visualization of the follow-up along the timescales chosen by using the plot method for Lexis objects. nicL is an object of class Lexis, so using the function plot() on it means that  ${\bf R}$  will look for the function plot.Lexis and use this function.

```
> plot( nicL )
```

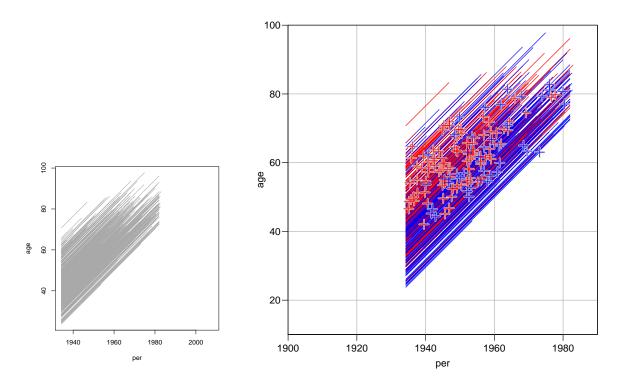

Figure 2: Lexis diagram of the nickel dataset, left panel the default version, the right one with bells and whistles. The red lines are for persons with exposure> 0, so it is pretty evident that the oldest ones are the exposed part of the cohort.

The function allows a lot of control over the output, and a points.Lexis function allows plotting of the endpoints of follow-up:

The results of these two plotting commands are in figure 2.

## 3 Splitting the follow-up time along a timescale

The follow-up time in a cohort can be subdivided by for example current age. This is achieved by the splitLexis (note that it is *not* called split.Lexis). This requires that the timescale and the breakpoints on this timescale are supplied. Try:

```
> nicS1 <- splitLexis( nicL, "age", breaks=seq(0,100,10) )
> summary( nicL )
```

#### Transitions:

To

From 0 1 Records: Events: Risk time: Persons: 0 542 137 679 137 15348.06 679

#### Rates:

To

From 0 1 Total 0 0 0.01 0.01

> summary( nicS1 )

#### Transitions:

To

From 0 1 Records: Events: Risk time: Persons: 0 2073 137 2210 137 15348.06 679

#### Rates:

То

From 0 1 Total 0 0 0.01 0.01

So we see that the number of events and the amount of follow-up is the same in the two datasets; only the number of records differ.

To see how records are split for each individual, it is useful to list the results for a few individuals:

#### > round( subset( nicS1, id %in% 8:10 ), 2 )

	lex.id	per	age	tfh	lex.dur	lex.Cst	lex.Xst	id	icd	exposure	dob
11	4	1934.25	47.91	23.19	2.09	0	0	8	527	9	1886.34
12	4	1936.34	50.00	25.28	10.00	0	0	8	527	9	1886.34
13	4	1946.34	60.00	35.28	9.68	0	0	8	527	9	1886.34
14	5	1934.25	54.75	24.79	5.25	0	0	9	150	0	1879.50
15	5	1939.50	60.00	30.04	10.00	0	0	9	150	0	1879.50
16	5	1949.50	70.00	40.04	6.84	0	0	9	150	0	1879.50
17	6	1934.25	44.33	23.04	5.67	0	0	10	163	2	1889.91
18	6	1939.91	50.00	28.71	10.00	0	0	10	163	2	1889.91
19	6	1949.91	60.00	38.71	2.54	0	1	10	163	2	1889.91

age1st agein ageout

- 11 24.72 47.91 69.68
- 12 24.72 47.91 69.68
- 13 24.72 47.91 69.68
- 14 29.96 54.75 76.84
- 15 29.96 54.75 76.84
- 16 29.96 54.75 76.84

```
17
    21.29 44.33
                  62.54
    21.29 44.33
                  62.54
18
19
    21.29 44.33
                  62.54
```

The resulting object, nicS1, is again a Lexis object, and so follow-up may be split further along another timescale. Try this and list the results for individuals 8, 9 and 10 again:

```
> nicS2 <- splitLexis( nicS1, "tfh", breaks=c(0,1,5,10,20,30,100) )</pre>
> round( subset( nicS2, id %in% 8:10 ), 2 )
```

22

If we want to model the effect of these timescales we will for each interval use either the value of the left endpoint in each interval or the middle. There is a function timeBand which returns these. Try:

```
> timeBand( nicS2, "age", "middle" )[1:20]
```

```
[1] 45 45 55 65 75 85 95 45 55 55 65 55 45 55 65 55 65 75

```

Note that these are the midpoints of the intervals defined by breaks=, not the midpoints of the actual follow-up intervals. This is because the variable to be used in modelling must be independent of the consoring and mortality pattern — it should only depend on the chosen grouping of the timescale.

## 4 Splitting time at a specific date

If we have a recording of the date of a specific event as for example recovery or relapse, we may classify follow-up time as being before of after this intermediate event. This is achieved with the function cutLexis, which takes three arguments: the time point, the timescale, and the value of the (new) state following the date.

Now we define the age for the nickel vorkers where the cumulative exposure exceeds 50 exposure years:

```
5 1934.246 54.7465 24.7890 22.0977
                                                  0
                                          0
                                                         5 9 150
                                                                          0

```

(The precursor.states= argument is explained below). Note that individual 6 has had his follow-up split at age 25 where 50 exposure-years were attained. This could also have been achieved in the split dataset nicS2 instead of nicL, try:

#### > subset( nicS2, id %in% 8:10 )

```

Note that follow-up subsequent to the event is classified as being in state 2, but that the final transition to state 1 (death from lung cancer) is preserved. This is the point of the

precursor.states= argument. It names the states (in this case 0, "Alive") that will be over-witten by new.state (in this case state 2, "High exposure"). Clearly, state 1 ("Dead") should not be updated even if it is after the time where the persons moves to state 2. In other words, only state 0 is a precursor to state 2, state 1 is always subsequent to state 2.

Note if the intermediate event is to be used as a time-dependent variable in a Cox-model, then lex.Cst should be used as the time-dependent variable, and lex.Xst==1 as the event.

## 5 Competing risks — multiple types of events

If we want to consider death from lung cancer and death from other causes as separate events we can code these as for example 1 and 2.

```
> data( nickel )
> nicL <- Lexis( entry = list( per=agein+dob,
                                age=agein,
                                tfh=agein-age1st),
                   exit = list( age=ageout ),
           exit.status = (icd > 0) + (icd %in% c(162,163)),
+
                   data = nickel )
> summary( nicL )

If we want to label the states, we can enter the names of these in the states parameter, try for example:

> summary( nicC, scale=1000 )

```
> nicL <- Lexis( entry = list( per=agein+dob,</pre>
                                 age=agein,
                                 tfh=agein-age1st),
                   exit = list( age=ageout ),
           exit.status = (icd > 0) + (icd %in% c(162,163)),
                   data = nickel,
                 states = c("Alive", "D.oth", "D.lung") )
> summary( nicL )

Note that the Lexis function automatically assumes that all persons enter in the first level (given in the states= argument)

When we cut at a date as in this case, the date where cumulative exposure exceeds 50 exposure-years, we get the follow-up *after* the date classified as being in the new state if the exit (lex.Xst) was to a state we defined as one of the precursor.states:

```
> nicL$agehi <- nicL$age1st + 50 / nicL$exposure
> nicC <- cutLexis( data = nicL,
                     cut = nicL$agehi,
               timescale = "age",
               new.state = "HiExp"
        precursor.states = "Alive" )
> subset( nicC, id %in% 8:10 )
          per
                          tfh lex.dur lex.Cst lex.Xst lex.id id icd exposure

From Alive HiExp D.oth D.lung Total
Alive 0 7.7 6.03 25.90 39.64
HiExp 0 0.0 15.74 47.21 62.94
```

Note that the persons-years is the same, but that the number of events has changed. This is because events are now defined as any transition from alive, including the transitions to HiExp.

Also note that (so far) it is necessary to specify the variable with the cutpoints in full, using only cut=agehi would give an error.

#### Subdivision of existing states

It may be of interest to subdivide the states following the intermediate event according to wheter the event has occurred or not. That is done by the argument split.states=TRUE.

Moreover, it will also often be of interest to introduce a new timescale indicating the time since intermediate event. This can be done by the argument new.scale=TRUE, alternatively new.scale="tfevent", as illustrated here:

```
> nicC <- cutLexis( data = nicL,
                      cut = nicL$agehi,
+
+
                timescale = "age",
               new.state = "Hi",
              split.states=TRUE, new.scale=TRUE,
        precursor.states = "Alive" )
> subset( nicC, id %in% 8:10 )
                                                            lex.Xst lex.id id icd

## 6 Multiple events of the same type (recurrent events)

Sometimes more events of the same type are recorded for each person and one would then like to count these and put follow-up time in states accordingly. Essentially, each set of cutpoints represents progressions from one state to the next. Therefore the states should be numbered, and the numbering of states subsequently occupied be increased accordingly.

This is a behaviour different from the one outlined above, and it is achieved by the argument count=TRUE to cutLexis. When count is set to TRUE, the value of the arguments new.state and precursor.states are ignored. Actually, when using the argument count=TRUE, the function countLexis is called, so an alternative is to use this directly.
